

## Introduction

- ▶ We consider **evaluation strategies** for **satisfiability planning**: find a (not necessarily shortest) plan.  
Trade-off: quality vs. cost to produce.
- ▶ Application domain: any approach to planning in which basic step is finding a plan of a given length, like planning as satisfiability, by CSP, by MILP, Graphplan, ...
- ▶ Significance: speed-ups of 0, 1, 2, 3, 4, ... orders of magnitude in comparison to the standard sequential evaluation strategy (as used in Graphplan, BLACKBOX, ...)

## SATP vs. heuristic state-space planning

Heuristic state-space search [Bonet & Geffner 2000] has been considered stronger than SATP on many **non-optimal** planning problems, but

- ▶ apples vs. oranges: SATP planners give optimality guarantees but planners like HSP do not, and
- ▶ nobody has used SATP planners for non-optimal planning.

### Open question

How efficient SATP actually is when optimality is not required?

## The standard sequential evaluation algorithm

Formula  $\phi_j$  represents the question *Is there a plan of length  $j$ ?*

**PROCEDURE** AlgorithmS()

$i := 0;$

**REPEAT**

test satisfiability of  $\phi_i;$

*IF*  $\phi_i$  is satisfiable **THEN** terminate;

$i := i + 1;$

**UNTIL** 1=0;

### Problem

This algorithm **proves** that the plan has optimal length!!!

## Evaluation Strategies for Planning as Satisfiability

Jussi Rintanen

Albert-Ludwigs-Universität Freiburg, Germany

August 26, ECAI'04

## Strengths of satisfiability planning (SATP)

Satisfiability planning (Kautz & Selman, 1992/96) is an efficient approach for solving inherently difficult planning problems:

- ▶ optimal solutions to otherwise easy problems  
(Most of the standard planning benchmarks are solvable non-optimally by simple poly-time algorithms!!!)
- ▶ hard problems in the phase transition region [Rintanen, KR'04]
- ▶ combinatorially difficult planning problems

## SATP for non-optimal planning

**Goal** Non-optimal planning: relax all optimality requirements, any plan will do!

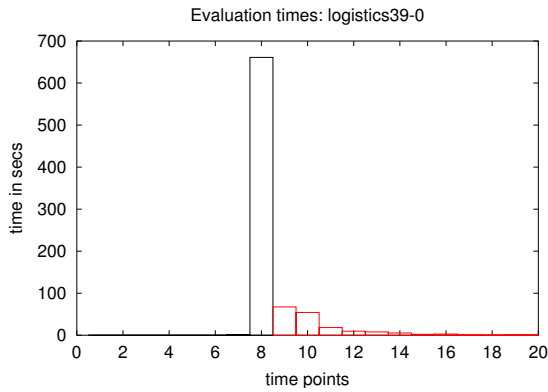

**Consequence** SATP becomes **extremely good** on standard big-and-easy benchmarks.

**Disclaimer** Problems that are **very easy** and **very big** likely remain to be solved by more specialized planning techniques: After all, SAT solvers are general-purpose problem solvers and cannot be as efficient as more specialized techniques on all types of problems.

## Experimentation

- ▶ How do runtime profiles of different benchmarks look like?
  1. benchmarks from planning competitions 1998, 2000, 2002
  2. samples from the set of all instances [Rintanen KR'04]
- ▶ Tests were run with Siegfried SAT solver version 4 (by Lawrence Ryan of University of Washington and Synopsys). This is one of the best SAT solvers for planning problems.

## Examples

Evaluation times: gripper10

August 26, ECAI'04 9 / 24

Experimentation

## Examples

(Albert-Ludwigs-Universität Freiburg)

Evaluation times: random6076

August 26, ECAI'04 11 / 24

Algorithms Algorithm A

## Algorithm A

- ▶  $n$  processes: evaluate  $n$  plan lengths simultaneously (starting from lengths 0 to  $n - 1$ )
- ▶ When a process finishes one length, it continues with the first unallocated one.
- ▶ Special case  $n = 1$  is Algorithm S.

(Albert-Ludwigs-Universität Freiburg)

August 26, ECAI'04 13 / 24

Algorithms Algorithm B

## Properties of Algorithm B

- ▶ The first unfinished formula gets  $1 - \gamma$  of the CPU. With  $\gamma = 0.9$  this is  $\frac{1}{10}$ , with  $\gamma = 0.5$  it is  $\frac{1}{2}$ .
- ▶ Speed-up is between  $1 - \gamma$  and  $\infty$ .  

$$\text{Speed-up} = \frac{\text{runtime with Algorithm S}}{\text{runtime with Algorithm B}}$$

Worst-case slow-down only a constant factor!  
 Speed-up can be arbitrarily high!!

(Albert-Ludwigs-Universität Freiburg)

August 26, ECAI'04 15 / 24

## Difficult problems with 20 state variables

- ▶ Sampled from the space of all problems instances with 20 state variables, 40 or 42 STRIPS operators each having 3 precondition literals and 2 effect literals.
- ▶ This is in the phase transition region [Rintanen, KR'04].
- ▶ We show here some of the most difficult instances.
- ▶ Easier instances are solved (by satisfiability planners) in milliseconds.

(Albert-Ludwigs-Universität Freiburg)

August 26, ECAI'04 10 / 24

Experimentation

## The important insight

- ▶ Characteristic shape:
- ▶ Most of the difficulty is in the **last unsatisfiable** formulae.
- ▶ Devise evaluation strategies that get to evaluate the easier satisfiable formulae early!!

(Albert-Ludwigs-Universität Freiburg)

August 26, ECAI'04 12 / 24

Algorithms Algorithm B

## Algorithm B

- ▶ Evaluate all plan lengths simultaneously at **different rates**.
- ▶ If rate of length  $n$  is  $r$ , evaluate length  $n + 1$  at rate  $\gamma r$ .  $\gamma$  is a constant  $0 < \gamma < 1$ .
- ▶ The CPU times allocated to the formulae form a geometric sequence

$$t\gamma^0, t\gamma^1, t\gamma^2, \dots$$

with a finite sum

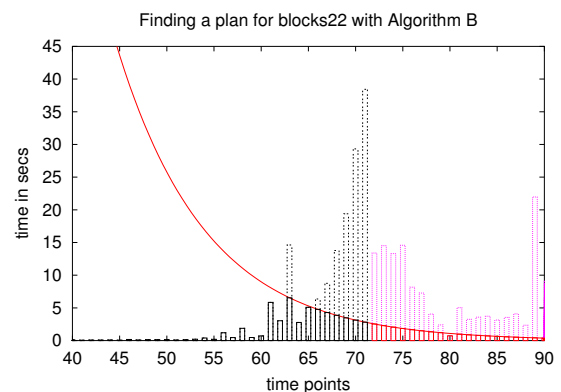

$$\frac{t}{1 - \gamma}$$

(Albert-Ludwigs-Universität Freiburg)

## Conclusions

- Our work makes the trade-off between plan quality and planning difficulty in satisfiability planning explicit.
- Possibility of **arbitrarily high performance gains** is obtained by accepting the **possibility of a small constant-factor slow-down** and the loss of guarantees for plan optimality.
- A planner based on the new evaluation algorithms and new efficient encodings [Rintanen, Heljanko & Niemelä 2005] outperforms Kautz & Selman's BLACKBOX by ...,3,4,5,6,... orders of magnitude on many problems.
