Lecture 1: Overview of Bayesian Modeling of Time-Varying Systems

Simo Särkkä

Department of Biomedical Engineering and Computational Science Aalto University

January 19, 2012

Contents

- Overview and History
- 2 Bayesian Estimation of Dynamic Processes
- Optimal Filtering
 - Applications
- 5 Probabilistic State Space Models
 - Regression Models
 - Time Series Models
 - Target Tracking Models
 - Further State Space Models

Summary and Demonstration

Contents of Course

- Modeling with stochastic state space models.
- Bayesian theory of optimal filtering.
- Gaussian approximations: Derivation of Kalman, extended Kalman and unscented Kalman filters, Gauss-Hermite and cubature Kalman filters from the general theory.
- Monte Carlo methods: Particle filtering, Rao-Blackwellized filtering.
- Optimal smoothing: Bayesian theory of optimal smoothing and related Kalman (=Gaussian) and particle type methods.
- Various illustrative applications to backup the theory.
- Various exercises to practice modeling and estimation.

- In 40's, Wiener's work on stochastic analysis and optimal filtering (and "cybernetics")
- In late 50's, state space models, Bellman's dynamic programming, Swerling's filter.
- In early 60's, Kalman filter and Kalman-Bucy filter, stability analysis of linear state space models (mostly by Kalman).
- In mid 60's, Rauch-Tung-Striebel smoother, extended Kalman filters (EKF).
- In late 60's, Bayesian approach to optimal filtering, first practical applications (e.g. Apollo program).
- In 70's and 80's, first particle filters, square root Kalman filters, new algorithms and applications.
- In 90's, rebirth of particle filters, sigma-point and unscented Kalman filters (UKF), new applications.
- In 00's, new algorithm variations and applications.

Recursive Estimation of Dynamic Process

- Dynamic, that is, time varying phenomenon for example the motion state of a car.
- The phenomenon is measured for example by a radar or by acceleration and angular velocity sensors.
- The purpose is to compute the state of the phenomenon when only the measurements are observed.
- The solution should be recursive, where the information in new measurements is used for updating the old information.

Bayesian Modeling of Dynamics

- The laws of physics, biology, epidemiology etc. are typically differential equations.
- Uncertainties and unknown sub-phenomena are modeled as stochastic processes:
 - Physical phenomena: differential equations + uncertainty
 stochastic differential equations.
 - Discretized physical phenomena: Stochastic differential equations ⇒ stochastic difference equations.
 - Naturally discrete-time phenomena: Systems jumping from step to another.
- Stochastic differential and difference equations can be represented in stochastic state space form.

Bayesian Modeling of Measurements

- The relationship between measurements and phenomenon is mathematically modeled as a probability distribution.
- The measurements could be (in ideal world) computed if the phenomenon was known (forward model).
- The uncertainties in measurements and model are modeled as random processes.
- The measurement model is the conditional distribution of measurements given the state of the phenomenon.

Why Bayesian Approach?

- Theory of optimal filtering can be formulated in many ways:
 - Least squares optimization framework ⇒ hard to extend recursive estimation beyond linear models, uncertainties cannot be modeled.
 - Maximum likelihood framework ⇒ the theoretical basis of dynamic models is somewhat heuristic, uncertainties cannot be modeled.
 - Bayesian framework ⇒ theory is quite complete, but the computational complexity can be unbounded.
- For practical "engineering" reasons, Bayesian approach is used here (because it works!).
- Kalman filter (1960) was originally derived in least squares framework
- Non-linear filtering theory has been Bayesian from the beginning (about 1964).

Bayesian Estimation of Dynamic Process

Time-varying process and noisy measurements from it:

Mathematical Model of Dynamic Process

• Generally, Markov model for the state:

 $\mathbf{x}_k \sim p(\mathbf{x}_k | \mathbf{x}_{k-1}).$

• Likelihood distribution of the measurement:

 $\mathbf{y}_k \sim p(\mathbf{y}_k \,|\, \mathbf{x}_k).$

• In principle, we could simply use the Bayes' rule

$$\rho(\mathbf{x}_1,\ldots,\mathbf{x}_T | \mathbf{y}_1,\ldots,\mathbf{y}_T) = \frac{\rho(\mathbf{y}_1,\ldots,\mathbf{y}_T | \mathbf{x}_1,\ldots,\mathbf{x}_T) \rho(\mathbf{x}_1,\ldots,\mathbf{x}_T)}{\rho(\mathbf{y}_1,\ldots,\mathbf{y}_T)}$$

• Curse of computational complexity: complexity grows more than linearly with number of measurements.

- The classical recursive (efficient) solution to the dynamic estimation problem is called the optimal filter.
- The optimal filter computes the (marginal) posterior distribution of the state given the measurements:

$$p(\mathbf{x}(t_k) | \mathbf{y}_1, \ldots, \mathbf{y}_k).$$

• The "filtered" state $\hat{\mathbf{x}}(t_k)$ typically is the posterior mean

$$\hat{\mathbf{x}}(t_k) = E(\mathbf{x}(t_k) | \mathbf{y}_1, \dots, \mathbf{y}_k).$$

• The solution is called filter for historical reasons.

Optimal Filtering, Prediction and Smoothing

- Recursively computable marginal distributions:
 - Filtering distributions:

$$p(\mathbf{x}_k | \mathbf{y}_1, \ldots, \mathbf{y}_k), \qquad k = 1, \ldots, T.$$

• Prediction distributions:

$$p(\mathbf{x}_{k+n} | \mathbf{y}_1, ..., \mathbf{y}_k), \qquad k = 1, ..., T, \quad n = 1, 2, ...,$$

• Smoothing distributions:

$$p(\mathbf{x}_k | \mathbf{y}_1, \ldots, \mathbf{y}_T), \qquad k = 1, \ldots, T.$$

• The mean can be computed exactly, as well as marginal moments, but cross-moments need extra effort.

Optimal Filtering, Prediction and Smoothing (cont.)

Algorithms for Computing the Solutions

- Kalman filter is the classical optimal filter for linear-Gaussian models.
- Extended Kalman filter (EKF) is linearization based extension of Kalman filter to non-linear models.
- Unscented Kalman filter (UKF) is sigma-point transformation based extension of Kalman filter.
- Gauss-Hermite and Cubature Kalman filters (GHKF/CKF) are numerical integration based extensions of Kalman filter.
- Particle filter forms a Monte Carlo representation (particle set) to the distribution of the state estimate.
- Grid based filters approximate the probability distributions by a finite grid.
- Mixture Gaussian approximations are used, for example, in multiple model Kalman filters and Rao-Blackwellized Particle filters.

Navigation of Lunar Module

- The navigation system of Eagle lunar module AGC was based on an optimal filter - this was in the year 1969.
- The dynamic model was Newton's gravitation law.
- The measurements at lunar landing were the radar readings.
- On rendezvous with the command ship the orientation was computed with gyroscopes and their biases were also compensated with the radar.
- The optimal filter was an extended Kalman filter.

Satellite Navigation (GPS)

- The dynamic model in GPS receivers is often the Newton's second law where the force is completely random, that is, the Wiener velocity model.
- The measurements are time delays of satellite signals.
- The optimal filter computes the position and the accurate time.
- Also the errors caused by multi path can be modeled and compensated.
- Acceleration and angular velocity measurements are sometimes used as extra measurements.

Spread of Disease

- Spreading of a disease in population can be modeled by differential equations.
 - Modeling the unknown parameters and phenomena as random processes leads to stochastic dynamic model.
 - The measurements in this case are the number of dead or recovered individuals.
- Optimal filter is used for computing the unknown parameters and the number of susceptible and infected individuals.
- It is also possible to predict when the maximum of the epidemic and how many casualties there will be.

Other Applications

- Target tracking, where one or many targets are tracked with many passive sensors - air surveillance.
- Time series prediction where the model parameters are estimated from the measured time series and the unknown part is predicted using these parameters.
- Analysis and restoration of audio signals.
- Telecommunication systems optimal receivers, signal detectors.
- State estimation of control systems chemical processes, auto pilots, control systems of cars.

Generic Probabilistic State Space Model

• General form of probabilistic state space models:

$$\mathbf{x}_k \sim p(\mathbf{x}_k | \mathbf{x}_{k-1})$$

 $\mathbf{y}_k \sim p(\mathbf{y}_k | \mathbf{x}_k)$
 $\mathbf{x}_0 \sim p(\mathbf{x}_0).$

- **x**_k is the generalized state at time step k, including all physical state variables and parameters.
- **y**_k is the vector of measurements obtained at time step *k*.
- The dynamic model p(x_k | x_{k-1}) models the dynamics of the state.
- The measurement model $p(\mathbf{y}_k | \mathbf{x}_k)$ models the measurements and their uncertainties.
- The prior distribution p(x₀) models the information known about the state before obtaining any measurements.

Linear Gaussian State Space Models

General form of linear Gaussian state space models:

$$\begin{split} \mathbf{x}_k &= \mathbf{A} \, \mathbf{x}_{k-1} + \mathbf{q}_{k-1}, \qquad \qquad \mathbf{q}_{k-1} \sim \mathsf{N}(\mathbf{0}, \mathbf{Q}) \\ \mathbf{y}_k &= \mathbf{H} \, \mathbf{x}_k + \mathbf{r}_k, \qquad \qquad \mathbf{r}_k \sim \mathsf{N}(\mathbf{0}, \mathbf{R}) \\ \mathbf{x}_0 &\sim \mathsf{N}(\mathbf{m}_0, \mathbf{P}_0). \end{split}$$

• In probabilistic notation the model is:

$$p(\mathbf{y}_k | \mathbf{x}_k) = \mathsf{N}(\mathbf{y}_k | \mathbf{H} \mathbf{x}_k, \mathbf{R})$$
$$p(\mathbf{x}_k | \mathbf{x}_{k-1}) = \mathsf{N}(\mathbf{x}_k | \mathbf{A} \mathbf{x}_{k-1}, \mathbf{Q}).$$

 Surprisingly general class of models – linearity is from measurements to estimates, not from time to outputs.

Non-Linear State Space Models

General form of non-linear Gaussian state space models:

$$\mathbf{x}_k = \mathbf{f}(\mathbf{x}_{k-1}, \mathbf{q}_{k-1})$$

 $\mathbf{y}_k = \mathbf{h}(\mathbf{x}_k, \mathbf{r}_k).$

- \mathbf{q}_k and \mathbf{r}_k are typically assumed Gaussian.
- Functions f(·) and h(·) are non-linear functions modeling the dynamics and measurements of the system.
- Equivalent to the generic probabilistic models of the form

$$\mathbf{x}_k \sim p(\mathbf{x}_k \,|\, \mathbf{x}_{k-1}) \ \mathbf{y}_k \sim p(\mathbf{y}_k \,|\, \mathbf{x}_k).$$

Modeling with State Space Models

- Probabilistic state space models are very general every finite dimensional Bayesian estimation problem has a state space representation.
- The most difficult task is figure out how to formulate an estimation problem in state space form.
- Formulating state space representations of physical problems is engineering in its basic form.
- Best way to learn this engineering is by examples and practical work – in this lecture we shall give examples.

Linear and Linear in Parameters Models

• Basic linear regression model with noise ϵ_k :

$$y_k = a_0 + a_1 x_k + \epsilon_k, \qquad k = 1, \ldots, N.$$

• First rename x_k to e.g. s_k to avoid confusion:

$$\mathbf{y}_k = \mathbf{a}_0 + \mathbf{a}_1 \, \mathbf{s}_k + \epsilon_k, \qquad k = 1, \dots, N.$$

• Define matrix $\mathbf{H}_k = (1 \ s_k)$ and state $\mathbf{x} = (a_0 \ a_1)^T$:

$$y_k = \mathbf{H}_k \mathbf{x} + \mathbf{e}_k, \qquad k = 1, \dots, N.$$

• For notation sake we can also define $\mathbf{x}_k = \mathbf{x}$ such that $\mathbf{x}_k = \mathbf{x}_{k-1}$:

$$\mathbf{x}_k = \mathbf{x}_{k-1}$$

 $y_k = \mathbf{H}_k \, \mathbf{x}_k + \mathbf{e}_k$

 Thus we have a linear Gaussian state space model, solvable with the basic Kalman filter.

Linear and Linear in Parameters Models (cont.)

• More general linear regression models:

$$y_k = a_0 + a_1 s_{k,1} + \dots + a_d s_{k,d} + \epsilon_k, \qquad k = 1, \dots, N.$$

Defining matrix H_k = (1 s_{k,1} ··· s_{k,d}) and state
 x_k = x = (a₀ a₁ ··· a_d)^T gives linear Gaussian state
 space model:

$$\mathbf{x}_k = \mathbf{x}_{k-1}$$
$$y_k = \mathbf{H}_k \, \mathbf{x}_k + \epsilon_k$$

• Linear in parameters models:

$$y_k = a_0 + a_1 f_1(s_k) + \cdots + a_d f_d(s_k) + \epsilon_k.$$

• Definitions $\mathbf{H}_k = (1 \ f_1(s_k) \ \cdots \ f_d(s_k))$ and $\mathbf{x}_k = \mathbf{x} = (a_0 \ a_1 \ \cdots \ a_d)^T$ again give linear Gaussian state space model.

Non-Linear and Neural Network Models

Non-linearity in measurements models arises in generalized linear models, e.g.

$$y_k = g^{-1}(a_0 + a_1 s_k) + \epsilon_k.$$

• The measurement model is now non-linear and if we define $\mathbf{x} = (a_0 \ a_1)^T$ and $h(\mathbf{x}) = g^{-1}(x_1 + x_2 \ s_k)$ we get non-linear Gaussian state space model:

$$\mathbf{x}_k = \mathbf{x}_{k-1}$$
$$y_k = h(\mathbf{x}_k) + \epsilon_k$$

- Neural network models such as multi-layer perceptron (MLP) models can be also transformed into the above form.
- Instead of basic Kalman filter we need extended Kalman filter or unscented Kalman filter to cope with the non-linearity.

Adaptive Filtering Models

 In digital signal processing, a commonly used signal model is the autoregressive model

$$\mathbf{y}_{k} = \mathbf{w}_{1} \, \mathbf{y}_{k-1} + \cdots + \mathbf{w}_{d} \, \mathbf{y}_{k-d} + \boldsymbol{\epsilon}_{k},$$

- In adaptive filtering the weights *w_i* are estimated from data.
- If we define matrix H_k = (y_{k-1} ··· y_{k-d}) and state as x_k = (w₁ ··· w_d)^T, we get linear Gaussian state space model:

$$\mathbf{x}_k = \mathbf{x}_{k-1}$$
$$y_k = \mathbf{H}_k \, \mathbf{x}_k + \epsilon_k$$

- The estimation problem can be solved with Kalman filter.
- The LMS algorithm can be interpreted as approximate version of this Kalman filter.

Adaptive Filtering Models (cont.)

 In time varying autoregressive models (TVAR) models the weights are time-varying:

$$\mathbf{y}_{k} = \mathbf{w}_{1,k} \, \mathbf{y}_{k-1} + \cdots + \mathbf{w}_{d,k} \, \mathbf{y}_{k-d} + \boldsymbol{\epsilon}_{k},$$

• Typical model for the time dependence of weights:

$$w_{i,k} = w_{i,k-1} + q_{k-1,i}, \quad q_{k-1,i} \sim N(0,\sigma^2), \quad i = 1, \dots, d.$$

• Can be written as linear Gaussian state space model with process noise $\mathbf{q}_{k-1} = (q_{k-1,1} \cdots q_{k-1,d})^T$:

$$\mathbf{x}_k = \mathbf{x}_{k-1} + \mathbf{q}_{k-1}$$
$$y_k = \mathbf{H}_k \, \mathbf{x}_k + \epsilon_k.$$

More general (TV)ARMA models can be handled similarly.

Spectral and Covariance Models

 Time series can be often modeled in terms of spectral density

 $S(\omega) = \{$ some function of angular velocity $\omega \}.$

• Or in terms of mean and covariance function:

$$\mathbf{m}(t) = \mathsf{E}[\mathbf{x}(t)]$$
$$\mathbf{C}(t, t') = \mathsf{E}[(\mathbf{x}(t) - \mathbf{m}(t)) (\mathbf{x}(t') - \mathbf{m}(t'))^T]$$

- Such Gaussian processes have representations as outputs of linear Gaussian systems driven by white noise.
- We often can construct a linear Gaussian state space model with a given spectral density or covariance function.
- If spectral density is a rational function, this is possible.

Stochastic Differential Equation Models

 Physical systems can be often modeled as differential equations with random terms such as

$$\frac{d\mathbf{x}(t)}{dt} = \mathbf{f}(\mathbf{x}, t) + \mathbf{L}(t) \, \mathbf{w}(t),$$

where $\mathbf{w}(t)$ is a continuous-time white noise process.

- The noise process can be used for modeling the deviation from the ideal solution $d\mathbf{x}(t)/dt = \mathbf{f}(\mathbf{x}, t)$.
- For example, locally (short term) linear functions, almost periodic functions, etc.
- The dynamic model has to be dicretized somehow in computations.
- Typically, measurements are assumed to be obtained at discrete instances of time:

$$\mathbf{y}_k = \mathbf{h}(\mathbf{x}(t_k)) + \mathbf{r}_k,$$

Time Series Prediction: CATS Benchmark (1/3)

An artificial time series with 5 000 data points was given.
 Within those 100 values were missing:

- The purpose was to predict the 100 missing values based on the other data.
- The performance criterion was the mean square error.

Time Series Prediction: CATS Benchmark (2/3)

- Model was build based on the following principles:
 - Long term behaviour was modeled with locally linear model:

$$\frac{d^2x(t)}{dt^2}=w(t),$$

• The dynamic model is equivalent to the linear difference equation model

$$\left(\begin{array}{c} x_k \\ \dot{x}_k \end{array}\right) = \left(\begin{array}{c} 1 & \Delta t \\ 0 & 1 \end{array}\right) \left(\begin{array}{c} x_{k-1} \\ \dot{x}_{k-1} \end{array}\right) + \left(\begin{array}{c} q_{1,k-1}^x \\ q_{2,k-1}^x \end{array}\right),$$

• The measurement model was simply

$$y_k = x_k + r_k^x$$
, $r_k^x \sim N(0, \sigma_x^2)$.

 The remaining residual periodicity was modeled with TVAR model (see the previous slides).

Time Series Prediction: CATS Benchmark (3/3)

- The parameters of linear state space models were estimated with cross-validation.
- Final prediction result was computed with Kalman filter and Rauch-Tung-Striebel smoother:

 This linear filtering solution worked better than any of the non-linear neural network estimators and won the competition!

Dynamic Model for a Car [1/3]

• The dynamics of the car in 2d (x₁, x₂) are given by the Newton's law:

 $\mathbf{f}(t)=m\mathbf{a}(t),$

where $\mathbf{a}(t)$ is the acceleration, *m* is the mass of the car, and $\mathbf{f}(t)$ is a vector of (unknown) forces acting the car.

We shall now model f(t)/m as a 2-dimensional white noise process:

$$d^{2}x_{1}/dt^{2} = w_{1}(t)$$

$$d^{2}x_{2}/dt^{2} = w_{2}(t).$$

Dynamic Model for a Car [2/3]

If we define x₃(t) = dx₁/dt, x₄(t) = dx₂/dt, then the model can be written as a first order system of differential equations:

$$\frac{\mathrm{d}}{\mathrm{d}t} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} = \underbrace{\begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}}_{\mathbf{F}} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} + \underbrace{\begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 1 & 0 \\ 0 & 1 \end{pmatrix}}_{\mathbf{L}} \begin{pmatrix} w_1 \\ w_2 \end{pmatrix}.$$

In shorter matrix form:

$$\frac{\mathrm{d}\mathbf{x}}{\mathrm{d}t} = \mathbf{F}\,\mathbf{x} + \mathbf{L}\,\mathbf{w}.$$

Dynamic Model for a Car [3/3]

- If the state of the car is measured (sampled) with sampling period ∆t it suffices to consider the state of the car only at the time instances t ∈ {0, ∆t, 2∆t, ...}.
- The dynamic model can be discretized, which leads to the linear difference equation model

$$\mathbf{x}_k = \mathbf{A} \, \mathbf{x}_{k-1} + \mathbf{q}_{k-1},$$

where $\mathbf{x}_k = \mathbf{x}(t_k)$, **A** is the transition matrix and \mathbf{q}_k is a discrete-time Gaussian noise process.

Measurement Model for a Car

Assume that the position of the car (x₁, x₂) is measured and the measurements are corrupted by Gaussian measurement noise e_{1,k}, e_{2,k}:

$$y_{1,k} = x_{1,k} + e_{1,k}$$

 $y_{2,k} = x_{2,k} + e_{2,k}$.

• The measurement model can be now written as

$$\mathbf{y}_k = \mathbf{H} \, \mathbf{x}_k + \mathbf{e}_k, \qquad \mathbf{H} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}$$

Model for Car Tracking

• The dynamic and measurement models of the car now form a linear Gaussian filtering model:

$$\mathbf{x}_k = \mathbf{A} \, \mathbf{x}_{k-1} + \mathbf{q}_{k-1}$$
$$\mathbf{y}_k = \mathbf{H} \, \mathbf{x}_k + \mathbf{r}_k,$$

where $\mathbf{q}_{k-1} \sim N(\mathbf{0}, \mathbf{Q})$ and $\mathbf{r}_k \sim N(\mathbf{0}, \mathbf{R})$.

• The posterior distribution is Gaussian

$$p(\mathbf{x}_k \,|\, \mathbf{y}_1, \ldots, \mathbf{y}_k) = \mathsf{N}(\mathbf{x}_k \,|\, \mathbf{m}_k, \mathbf{P}_k).$$

 The mean **m**_k and covariance **P**_k of the posterior distribution can be computed by the Kalman filter.

Re-Entry Vehicle Model [1/3]

Gravitation law:

$$\mathbf{F} = m\mathbf{a}(t) = -\frac{G \, m \, M \, \mathbf{r}(t)}{|\mathbf{r}(t)|^3}.$$

• If we also model the friction and uncertainties:

$$\mathbf{a}(t) = -\frac{GM\mathbf{r}(t)}{|\mathbf{r}(t)|^3} - D(\mathbf{r}(t))|\mathbf{v}(t)|\mathbf{v}(t) + \mathbf{w}(t).$$

Re-Entry Vehicle Model [2/3]

• If we define $\mathbf{x} = (x_1 \ x_2 \ \frac{dx_1}{dt} \ \frac{dx_2}{dt})^T$, the model is of the form

$$\frac{\mathrm{d}\mathbf{x}}{\mathrm{d}t} = \mathbf{f}(\mathbf{x}) + \mathbf{L}\,\mathbf{w}(t).$$

where $f(\cdot)$ is non-linear.

• The radar measurement:

$$r = \sqrt{(x_1 - x_r)^2 + (x_2 - y_r)^2} + e_\theta$$
$$\theta = \tan^{-1}\left(\frac{x_2 - y_r}{x_1 - x_r}\right) + e_\theta,$$

where $e_r \sim N(0, \sigma_r^2)$ and $e_{\theta} \sim N(0, \sigma_{\theta}^2)$.

Re-Entry Vehicle Model [3/3]

 By suitable numerical integration scheme the model can be approximately written as discrete-time state space model:

$$\begin{aligned} \mathbf{x}_k &= \mathbf{f}(\mathbf{x}_{k-1}, \mathbf{q}_{k-1}) \\ \mathbf{y}_k &= \mathbf{h}(\mathbf{x}_k, \mathbf{r}_k), \end{aligned}$$

where \mathbf{y}_k is the vector of measurements, and $\mathbf{q}_{k-1} \sim N(\mathbf{0}, \mathbf{Q})$ and $\mathbf{r}_k \sim N(\mathbf{0}, \mathbf{R})$.

 The tracking of the space vehicle can be now implemented by, e.g., extended Kalman filter (EKF), unscented Kalman filter (UKF) or particle filter.

Further State Space Models

- Multiple target tracking (remote surveillance)
 - Target dynamics are modeled with stochastic difference or differential equations.
 - The measurements arrive at irregular intervals.
 - The number of targets in unknown.
 - Data association indicators are also unknown latent variables.
- Bus and bus stop tracking
 - Bus dynamics are modeled with stochastic difference or differential equations.
 - Measurements from GPS, odometer, gyroscope and acceleration sensors.
 - The index of the current bus stop is an unknown variable to be estimated.
 - The known order of bus stops is used as additional information in form of hidden Markov model (HMM).

Further State Space Models (cont.)

- Tracking of objects in images
 - Object position and pose can be modeled with difference or differential equations.
 - Data representation can be, e.g., spline approximation of the object contour.
 - The measurement model is a complicated likelihood, which depends on object identification algorithm etc.
- Monitoring of chemical processes
 - Reaction kinetics are modeled with stochastic differential equations.
 - The measurements can be highly non-linear functions of the state.
 - Processes typically contain unknown physical parameters.

Summary

- The purpose of is to estimate the state of a time-varying system from noisy measurements obtained from it.
- The linear theory dates back to 50's, non-linear Bayesian theory was founded in 60's.
- The efficient computational solutions can be divided into prediction, filtering and smoothing.
- Applications: tracking, navigation, telecommunications, audio processing, control systems, etc.
- The formal Bayesian estimation equations can be approximated by e.g. Gaussian approximations, Monte Carlo or Gaussian mixtures.
- Formulating physical systems as state space models is a challencing engineering topic as such.

Matlab Demo: EKF/UKF Toolbox

http://www.lce.hut.fi/research/mm/ekfukf/
